Methodological Rigor: Participation & Non-Response Bias Audit

To validate the external generalizability of this study and evaluate potential threats from non-response or selection bias, a rigorous temporal proxy assessment was executed. Following established econometric validation frameworks, the response index was split symmetrically using the chronological entry median as the breaking line. This segmenting establishes two equal horizons: the **Early Response Cohort** and the **Late Response Cohort**.

In survey methodology, late respondents are structurally treated as a reliable proxy framework for non-respondents. Demonstrating that individuals who required subsequent systemic reminders or longer reflection windows exhibit homogenous answer structures to early adopters mathematically minimizes the likelihood of systematic selective non-response distortion.

320	160	160
TOTAL CHECKED CASES	EARLY HORIZON COUNT (N)	LATE HORIZON COUNT (N)

Proportional Visual Divergence Diagnostic

The stacked horizontal distribution analysis below provides a granular visualization of how the specific response patterns behave across the temporal horizons for target Question ID 22.

Statistical Interpretation Framework

A high degree of visual symmetry or proportional structural tracking between the early and late bars signifies data population invariance. When cohort distribution flags mirror one another, the data collection pipeline is confirmed to be stable and clean of selection tracking anomalies.

Conversely, substantial asymmetric clustering inside a specific block would signify that late adopters hold structurally distinct viewpoints, prompting the need for specialized categorical control weights inside final estimation regressions. For this specific analytical pass, the data demonstrates robust compositional stability across both waves.
